(54) Method of forming insulating films, capacitances, and semiconductor devices.

(57) Insulating metal oxide or nitride films are deposited by RF magnetron sputtering. During sputtering, the atmospheric gas comprises an oxygen or nitride compound gas and an inert gas. The proportion of the inert gas is decreased to 25 atom% or lower. By this sputtering condition, adverse effects caused by the inert gas is suppressed so that the quality of the insulating film is substantially improved.

### FIG. 1(A)

EP 0 468 758 A1

Jouve, 18, rue Saint-Denis, 75001 PARIS

The present invention relates to a method of forming insulating films in general. More particularly, it relates to such a method of sputtering suitable for forming excellent dielectric films suitable for use in capacitances.

In the recent years, dielectric (insulating) films deposited by CVD have been utilized to form capacitances for use in integrated semiconductor devices. The employment of CVD makes it possible to deposit dielectric films at low temperatures up to 450°C so that inexpensive substrates such as soda lime glass or borosilicate glass substrates can be used. Similar low temperature deposition can be accomplished also by plasma CVD and sputtering in an atmosphere comprising an inert gas such as argon at a density of 100% to 80%. The use of argon has been known to increase the sputtering yield.

In accordance with experiments of the inventor, it has been found that the number of the interface states occurring between the dielectric film and the underlying electrical active region seriously depends upon the argon density of the sputtering atmosphere. A conspicuous example is the case of dielectric films made of tantalum oxide. In this case, many clusters of tantalum atoms of 5 to 50 Å diameter are formed in the oxide film due to stability of metal tantalum. It has been also found that the argon density significantly influences the difference in flat band voltage from the ideal value which indicates the degradation of the film and reflects the state number of fixed charge and the clusters.

There are other attempts to form dielectric films by the use of photo-CVD. In this case, the underlying surface is less damaged and the density of interface states is as low as  $2 \times 10^{10} \text{eV}^{-1} \text{cm}^{-2}$ . On the other hand, the deposition of photo-CVD takes much time to complete due to very slow deposition speed so as not to be utilized for mass production. Furthermore, the long-term reliability is not assured because of the hot-electron effect resulting from hydrogen utilized during deposition.

It would therefore be desirable:

to provide a method of forming high quality insulating films by deposition at low temperatures suitable for use in capacitances;

to provide a method of forming high quality insulating films having high reliability; and

to provide a method of forming a semiconductor device having high reliability.

Additional advantages and novel features of the present invention will be set forth in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following or may be learned by practice of the present invention. The advantages of the invention may be realized and attained by means of the instrumentalities and combinations particularly pointed out in the appended claims.

In accordance with the present invention, as embodied and broadly described herein, a dielectric material or an insulating material is sputtered on a substrate in a particularly appropriate atmosphere.

Unlike conventional processes, the atmosphere is characterized in that no or a small proportion of an inert gas, typically argon, is utilized. The inventors have presumed that the disadvantages of argon atoms include stoichiometric disturbance in the product of sputtering and damage or defects caused by collision of argon ions or argon atoms with the dielectric film resulting in formation of fixed charge

In the case of sputtering of a metal oxide such as tantalum oxide, titanium oxide or other suitable oxide dielectric materials and barium titanate, lead titanate or similar ferroelectric materials, the inside of a sputtering apparatus is filled with an oxidizing gas containing an inert gas at 25 vol.% or less, e.g. a mixture of oxygen (100% to 75% in volume) and argon (0% to 25% in volume). Other suitable oxidizing gases include  $\text{N}_2\text{O}$  and  $\text{O}_3$ . Particularly, in the case of  $\text{O}_2$  or  $\text{O}_3$ , unnecessary atoms are not introduced into the oxide film resulting in few pinholes, little damage to dielectric properties and decreased dispersion in dielectric strength.  $\text{O}_3$  tends to be decomposed to yield oxygen radicals which enhance progress of the deposition. Usually, a bulk of a desired one of these oxides is used as the target of the sputtering. A simple metal such as tantalum can be also used as the target by suitably selecting the sputtering condition as explained in the following detailed description.

In the case of sputtering of nitrides, e.g. insulating nitrides such as silicon nitride and aluminum nitride, or resistive nitrides such as tantalum nitride, titanium nitride or other suitable nitride, the inside of a sputtering apparatus is filled with a nitride compound gas containing an inert gas at 50 vol.% or less, preferably 25 vol.% or less, e.g. a mixture of nitrogen (100 vol.% to 75 vol.%) and argon (0 vol.% to 25 vol.%). Other suitable nitride compound gases include ammonia ( $\text{NH}_3$ ). Particularly, when very pure nitrogen such as vaporized from liquid nitrogen is used, unnecessary atoms are not introduced into the nitride film resulting in few pinholes, little damage to dielectric property and small dispersion in dielectric strength.

The quality of insulating films can be furthermore improved by using a halogen which would terminate dangling bonds and neutralize alkali ions inadvertently introduced into the films. In this case, a halogen compound gas is introduced together with the process gas into the sputtering apparatus at 0.2 to 20 vol%. The halogen compound gases include fluorine compounds such as  $\text{NF}_3$ ,  $\text{N}_2\text{F}_4$ ,  $\text{HF}$ , chloro-fluoro carbon and  $\text{F}_2$  and chlorine compounds such as  $\text{CCl}_4$ ,  $\text{Cl}_2$  and  $\text{HCl}$ . If too much halogen is introduced, the content of the insulating film might be altered. The concentration of the halogen is limited to 0.01 to 5 atoms in general.

The accompanying drawings, together with the

description, serve to explain the principles of the invention, wherein:

Fig. 1(A) is a side view showing a MIS (metal-insulator-semiconductor) device manufactured in accordance with a first embodiment of the present invention;

Fig. 1(B) is a graph for explaining the displacement of the flat band voltage;

Fig. 2 is a graph showing the displacement of the flat band voltage versus the argon proportion to an argon and O<sub>2</sub> mixture in the sputtering atmosphere;

Figs. 3(A) and 3(B) are side views showing a capacitance manufactured in accordance with a second embodiment of the present invention;

Fig. 4 is a graph showing the dielectric strength versus the argon proportion in the sputtering atmosphere;

Fig. 5 is a graph showing the relative dielectric constant versus the argon proportion in the sputtering atmosphere;

Fig. 6 is a cross-sectional view showing a DRAM provided with a capacitance manufactured in accordance with the first or second embodiment of the present invention;

Fig. 7 is a cross-sectional view showing another example of DRAM provided with a capacitance manufactured in accordance with the first or second embodiment of the present invention; and

Fig. 8 is a graph showing the displacement of the flat band voltage versus the argon proportion to an argon and N<sub>2</sub> mixture in the sputtering atmosphere.

Referring now to Figs. 1(A) and 1(B) and Fig. 2, a method of manufacturing an insulating film in accordance with a first embodiment of the present invention will be explained. A substrate 1 made of a single-crystal silicon semiconductor is disposed on a substrate holder in an RF magnetron sputtering apparatus (not shown) in which a target of Ta<sub>2</sub>O<sub>5</sub> has been mounted on a target holder in advance. After evacuating the inside of the apparatus, a gas is introduced therein in order to prepare a suitable atmosphere for gas discharge. The gas comprises argon and an oxidizing gaseous compound such as oxygen. Desirably, the constituent gases have 99.999% or higher purities. A tantalum oxide film 3 (insulating film) is then sputtered on the substrate 1 by causing gas discharge between the target holder and the substrate holder. After completion of deposition, the substrate 1 is removed from the apparatus and coated with a circular aluminum electrode 4 having a 1mm diameter by electron beam evaporation.

The characteristics of such insulating film in the MIS structure (Al-Ta<sub>2</sub>O<sub>5</sub>-Si) can be evaluated by displacement  $\Delta V_{FB}$  of the flat band voltage through measuring the flat band voltage. For the measurement of the displacement, the insulating film is given

BT (bias-temperature) treatment with a negative bias voltage of  $2 \times 10^6$  V/cm at 150°C for 30 minutes followed by measuring the flat band voltage  $V_{FB1}$ , and thereafter BT treatment with a positive bias voltage of  $2 \times 10^6$  V/cm at 150°C for 30 minutes followed by measuring the flat band voltage  $V_{FB2}$  again. The displacement  $\Delta V_{FB}$  is  $|V_{FB1} - V_{FB2}|$  as illustrated in Fig. 1(B).

The above procedure of deposition was repeated by changing the proportion of argon to oxygen from 100% to 0% for reference. The displacements  $\Delta V_{FB}$  measured are plotted graphically in Fig. 2. As shown in the diagram, the displacement  $\Delta V_{FB}$  significantly decreased below 5 V when the argon proportion was decreased to 25% or lower. When argon was not used, i.e. pure oxygen (100%) was used, the displacement  $\Delta V_{FB}$  was only 0.5V or lower. Contrary to this, when pure argon (100%) was used, the displacement  $\Delta V_{FB}$  was increased to 10V. The displacement  $\Delta V_{FB}$  was furthermore abruptly decreased to several tenths thereof by utilizing an additive of a halogen. The introduction of a halogen is carried out by introducing into the sputtering apparatus, together with oxygen, a halogen compound gas such as a nitrogen fluoride (NF<sub>3</sub>, N<sub>2</sub>F<sub>4</sub>) at 0.2 to 20 vol%. Particularly, NF<sub>3</sub> is most preferred because NF<sub>3</sub> can be handled with a little care and decomposed by low energy.

Referring next to Fig. 3, a method of manufacturing an insulating film in accordance with a second embodiment of the present invention will be explained. A substrate 1 comprising a soda-lime glass plate and a SiO<sub>2</sub> blocking film formed thereon is disposed in a sputtering apparatus in which a target of metal tantalum has been set up in advance. After evacuating the inside of the apparatus, a gas is introduced therein for gas discharge. The gas comprises argon. A tantalum film 2 in the form of an island (lower electrode) is sputtered on the substrate to a thickness of 2000 Å on the substrate 1 with the aid of a metallic mask by causing gas discharge between the target holder and the substrate holder. Alternatively, a known photolithography may be utilized instead of the use of the metallic mask. The substrate temperature is 350°C. The pressure of the gas is maintained at 0.06 Torr during deposition. The input RF energy is 100W at 13.56 MHz.

After completion of deposition of the lower electrode 2, the gas is replaced by a mixture of oxygen (100 vol% to 0 vol%) and argon (0 vol% to 100 vol%). The Ta target is also replaced by a Ta<sub>2</sub>O<sub>5</sub> target having a 99.99% or higher purity. A tantalum oxide film 3 (insulating film) is then deposited on the lower electrode 2 by sputtering associated with gas discharge between the target holder and the substrate holder. The substrate temperature is 100°C. The pressure of the gas is maintained at 0.05 Torr during deposition. The input RF energy is 500W at 13.56 MHz. The distance between the substrate 1 and the target is adjusted.

ted to be 150mm. After completion of deposition, the substrate 1 is removed from the apparatus and coated with a circular aluminium film 4 (upper electrode) having a 1mm diameter by electron beam evaporation in order to form a capacitance comprising the lower and upper electrodes 2 and 4 and the interposed insulating (dielectric) film 3.

The characteristics of such a capacitance were also evaluated by measuring the displacement  $\Delta V_{FB}$  of the flat band voltage. When 100% oxygen was used, an excellent capacitance was formed. Even if argon was used up to 25%, capacitances having equivalent qualities were formed by setting the distance between the substrate 1 and the target to be larger than the appropriate value for the case of deposition using pure oxygen. Accordingly, excellent capacitances can be formed by utilizing a mixture of oxygen (100 vol% to 25 vol%) and argon (0 vol% to 75 vol%). The quality of such insulating films can be furthermore improved by introducing a halogen in the same manner as explained in conjunction with the first embodiment. In this case, the introduced halogen atoms can be activated by flash annealing using excimer laser pulses so that dangling bonds occurring in the film are neutralized by the halogen atoms and the origin of fixed charge in the film is eliminated.

Fig.4 is a graph showing the relationship between the dielectric strength of the film 3 and the oxygen proportion to the argon-oxygen mixture. The dielectric strength is measured as the threshold voltage when the current leakage exceeds 1  $\mu A$ . In this diagram, the length of vertical lines corresponds to double the standard deviations  $\sigma(X)$  and given center dots indicative of averages respectively. As shown in the diagram, the  $\sigma(X)$  decreased and the average dielectric strengths increased as the proportion increased beyond 75%. Fig.5 is a graph showing the relationship between the relative dielectric constant of the film 3 and the oxygen proportion to the argon-oxygen mixture in the same manner. In this diagram, it is also understood that high proportions of oxygen are advantageous resulting in small dispersions.

Referring next to Fig.6, a suitable application of the insulating film formed in accordance with the first or second embodiment of the present invention will be explained. The insulating film is used to form storage capacitances coupled with gate -insulated field-effect transistors for constructing a DRAM (dynamic random access memory) of 1 Tr/Cell type.

A storage element of the DRAM is of a stacked type as illustrated in Fig.6 and comprises an n-type silicon semiconductor substrate within which a source and drain regions 8 and 9 of p-type are formed in order to define a channel region therebetween, a field-insulating film 5 (LOCOS) for insulating the element from adjacent elements, a gate electrode 7 formed on the channel region through a gate -insulating film 6 formed by thermal oxidation or sputtering of silicon

oxide in 100% oxygen, an interlayer insulation film 14, a lower electrode 10 made of a silicon semiconductor heavily doped with phosphorus, a dielectric (insulating) film 11 and an upper electrode 12 formed of an aluminum film or a dual film comprising an aluminum layer and a tantalum layer.

The lower electrode 10 may be formed of metal tantalum, tungsten, titanium, molybdenum or any silicides of such metals and makes electrical contact with the drain region 9 through an opening formed in the interlayer film 14. The dielectric film 11 is formed of a  $Ta_2O_5$  film deposited by sputtering to a thickness of 300 Å to 3000 Å, preferably 500 Å to 1500 Å, e.g. 1000 Å in accordance with the first or second embodiment as described above. The gate-insulating film 6 can be made also from  $Ta_2O_5$  in place of silicon oxide. In that case, the number of interface states is as small as  $2 \times 10^{10} cm^{-2}$ . A storage capacitance is formed of the upper and lower electrodes 10 and 12 and the dielectric film 11 located therebetween. The formation of trapping centers of hot carriers can be avoided by forming these electrodes 10 and 12 and the dielectric film 11 in an atmosphere which has been deprived of hydrogen, which otherwise could reach to the gate-insulating film by drifting (diffusion). The channel length of the element is selected between 0.1  $\mu m$  and 1.0  $\mu m$ , e.g. 0.5  $\mu m$ , so that one storage element can be formed within an area of 20  $\mu m$  square. The source region 8 is connected to a bit line for example, and in that case the gate electrode 7 is connected to an address line of the memory. Such miniaturized structure becomes possible due to the large storage capacitance originating from the large relative dielectric constant ( $\approx 27$ ) of the tantalum oxide film as compared to the relative dielectric constant ( $\approx 3.8$ ) of silicon oxide. The large relative dielectric constant makes it possible to increase the thickness of the dielectric film to e.g. 1000 Å so that electric insulation is improved and the number of pinholes is decreased. The frequency property of the tantalum oxide film is also excellent and maintained even at high frequencies. In the figure, numeral 12' designates an extension of the upper electrode of an adjacent storage element. Numeral 13 is the bit line of an adjacent element.

Referring next to Fig.7, another application of the insulating film formed in accordance with the first or second embodiment of the present invention will be explained. The insulating film is used to form storage capacitances for a DRAM (dynamic random access memory) of 1 Tr/Cell type.

A storage unit element of the DRAM illustrated in Fig.7 can store information of two bits. The element comprises a p-type silicon semiconductor substrate within which a pair of channel regions 15 and 15' of n-type and a pair of drain regions 8 and 8' of p-type are formed, a plateau of a p-type semiconductor material forming a source region 9 located between the

channel regions 15 and 15', a source electrode 19 formed on the plateau, a pair of gate electrodes 7 and 7' formed on the channel regions 15 and 15' through a gate-insulating film 6 and flanking the side surface of the source region 9, a field insulating film 5 (LOCOS) for insulating the element from adjacent elements, an interlayer insulation film 14, a pair of lower electrodes 10 and 10' made of silicon semiconductor heavily doped with phosphorus, a dielectric (insulating) film 11 and a pair of upper electrodes 12 and 12' formed of an aluminum film or a dual film comprising an aluminum layer and a tantalum layer. The channel regions 15 and 15' are formed by ion implantation of boron with a mask of the plateau 9 and 19 and the field insulating film 5 to a density of  $1 \times 10^{15} \text{ cm}^{-3}$  to  $5 \times 10^{16} \text{ cm}^{-3}$ , in advance of the formation of the gate electrodes 7 and 7', followed by ion implantation of phosphorus into the regions 8 and 8' with a mask of the plateau 9 and 19, the field-insulating film 5 and the gate electrodes 7 and 7' to a density of  $1 \times 10^{19} \text{ cm}^{-3}$  to  $1 \times 10^{21} \text{ cm}^{-3}$ .

The lower electrodes 10 and 10' make electric contact with the drain regions 8' and 8 through openings formed in the interlayer film 14 respectively. The dielectric film 11 is formed of a  $\text{Ta}_2\text{O}_5$  film deposited by sputtering to a thickness of 300 Å to 3000 Å, preferably 500 Å to 1500 Å, e.g. 1000 Å in accordance with the first or second embodiment as described above in the same manner as that of the previous application. The lower electrode may be formed of metal tantalum, tungsten, titanium, molybdenum or any silicides of these metals in place of the doped silicon semiconductor. A pair of storage capacitances 21 and 21' are formed from the upper and lower electrodes 10, 10' and 12, 12' and the dielectric film 11 therebetween. The channel length of the element is selected between 0.1 µm and 1.0 µm, e.g. 0.5 µm so that a two bit storage element can be formed within an area of 10 to 20 µm square.

Next, a method of manufacturing an insulating film in accordance with a third embodiment of the present invention will be explained. Fig.1(A) is used again for this purpose. A substrate 1 made of a single-crystal silicon semiconductor is disposed on a substrate holder in an RF magnetron sputtering apparatus (not shown) in which a target of  $\text{Si}_3\text{N}_4$  has been mounted on a target holder in advance. Alternatively, the target may be made of other nitrides such as aluminum nitride, tantalum nitride, titanium nitride instead of the  $\text{Si}_3\text{N}_4$  target. After evacuating the inside of the apparatus, a gas is introduced thereinto in order to prepare a suitable atmosphere for gas discharge. The gas comprises argon and a nitrogen compound gas such as nitrogen. Desirably, the constituent gases have 99.9% or higher purities. The substrate temperature is 200°C. The pressure of the gas is maintained at 0.05 Torr during deposition. The input RF energy is 500W at 13.56 MHz. The distance be-

tween the substrate 1 and the target is adjusted to be 150mm. A silicon nitride film 3 (insulating film) is then sputtered on the substrate 1 by causing gas discharge between the target holder and the substrate holder. After completion of deposition, the substrate 1 is removed from the apparatus and coated with a circular aluminum electrode 4 having a 1mm diameter by electron beam evaporation.

The characteristics of such insulating film in the MIS structure ( $\text{Al-Si}_3\text{N}_4\text{-Si}$ ) can be evaluated by displacement  $\Delta V_{\text{FB}}$  of the flat band voltage through measuring the flat band voltage. For the measurement of the displacement, the insulating film is given BT (bias-temperature) treatment with a negative bias voltage of  $2 \times 10^6 \text{ V/cm}$  at 150°C for 30 minutes followed by measuring the flat band voltage, and thereafter BT treatment with a positive bias voltage of  $2 \times 10^6 \text{ V/cm}$  at 150°C for 30 minutes followed by measuring the flat band voltage again in the same manner as for oxide films.

The above procedure of deposition was repeated by changing the proportion of argon to nitrogen from 100% to 0% for reference. The displacements  $\Delta V_{\text{FB}}$  measured are plotted on a graphical diagram shown in Fig.8. As shown in the diagram, the displacements  $\Delta V_{\text{FB}}$  significantly decreased below 2 V when the argon proportion was decreased to 25% or lower. Numeral 31 designates a displacement of 11.5V in the case of a silicon nitride film deposited by a conventional plasma CVD for reference. When argon was not used, i.e. pure nitrogen (100%) was used, the displacements  $\Delta V_{\text{FB}}$  was only 0.5V or lower as depicted by numeral 34. Contrary to this, when pure argon (100%) was used, the displacements  $\Delta V_{\text{FB}}$  was increased to 13V. The displacements  $\Delta V_{\text{FB}}$  was furthermore abruptly decreased to several tenths thereof by utilizing an additive of a halogen. The introduction of a halogen is carried out by introducing into the sputtering apparatus, together with nitrogen, a halogen compound gas such as a nitrogen fluoride ( $\text{NF}_3$ ,  $\text{N}_2\text{F}_4$ ) at 0.2 to 20 vol%. In this case, the introduced halogen atoms can be activated by flash annealing using excimer laser pulses so that dangling bonds occurring in the film are neutralized by the halogen atoms and the origin of fixed charge in the film is eliminated.

Referring again to Figs.6 and 7, suitable applications of the insulating film formed in accordance with the third embodiment of the present invention will be explained. The insulating film is used also in this case to form storage capacitances for DRAMs (dynamic random access memory) of 1 Tr/Cell type. The explanation is substantially same as given to the above applications utilizing the tantalum oxide insulating films except for the following description.

The dielectric film 11 as illustrated in Figs.6 and 7 is formed of a  $\text{Si}_3\text{N}_4$  film in this case deposited by sputtering to a thickness of 300 Å to 3000 Å, preferably 500 Å to 1500 Å, e.g. 1000 Å in accordance with

the third embodiment as described above. The gate-insulating film 6 can be made also from  $\text{Si}_3\text{N}_4$  in place of silicon oxide. In that case, the number of interface states is as small as  $3 \times 10^{10}\text{cm}^{-2}$ . The dimension of the unit elements can be decreased in the same manner as in the applications utilizing the tantalum oxide films due to the large storage capacitance originating from the large relative dielectric constant ( $\approx 6$ ) of the silicon nitride film as compared to the relative dielectric constant ( $\approx 3.8$ ) of silicon oxide.

The foregoing description of preferred embodiments has been presented for purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form described, and obviously many modifications and variations are possible in light of the above teaching. The embodiments were chosen in order to explain most clearly the principles of the invention and its practical application thereby to enable others in the art to utilize most effectively the invention in various embodiments and with various modifications as are suited to the particular use contemplated.

Although the dielectric films are deposited by RF magnetron sputtering in the above preferred embodiments, other suitable sputtering can be utilized, e.g. various known types of DC or RF sputtering methods. It is partly because of the high resistance of the targets utilized that RF magnetron sputtering is preferred. Pure metals such as tantalum and titanium, however, may be used in suitable sputtering conditions. In the case of deposition of oxide films by the use of such targets of pure metals, the atmosphere is purified to a 99.999% or higher purity and comprises 100% to 90% oxygen in which deposition of the oxide films is carried out with a lower acceleration voltage at a lower deposition speed of the order of 1/4 of the above embodiments.

The application of the present invention is not limited to the above examples but applicable for integrated circuits utilizing the capacitors of the present invention, transistors of inversed-stagger type, vertical channel transistors, other types of insulated-gate field-effect transistors formed within a single-crystal silicon semiconductor substrate and so forth. The capacitances can be formed into a multi-layered structure or vertical type structure in which the dielectric film is sandwiched by a pair of electrodes in a lateral direction. The capacitors of the present invention can be used for dynamic memories.

## Claims

1. A method of forming an insulating oxide film comprising:
  - disposing a substrate to be coated and a target made of a metal or an oxide thereof in a sputtering apparatus; and
  - sputtering an oxide film on said substrate in an atmospheric gas including an oxidizing gas at a proportion not lower than 75%.
2. A method as claimed in claim 1, wherein said target comprises oxide selected from the group consisting of tantalum oxide, titanium oxide, barium titanate and lead titanate.
3. A method as claimed in claim 1, wherein said target is a metal selected from the group consisting of titanium and tantalum.
4. A method as claimed in any one of claims 1 to 3, wherein said oxidizing gas is a gas selected from the group consisting of oxygen,  $\text{N}_2\text{O}$ , and  $\text{O}_3$ .
5. A method as claimed in any one of claims 1 to 4, wherein said atmospheric gas is pure oxygen.
6. A method of forming insulating nitride films comprising:
  - disposing a substrate to be coated and a target in a sputtering apparatus; and
  - sputtering a nitride film on said substrate in an atmospheric gas including a nitrogen-containing gas at a proportion not lower than 50%.
7. A method as claimed in claim 6, wherein said target comprises nitride selected from the group consisting of silicon nitride, tantalum nitride, and titanium nitride.
8. A method as claimed in claim 6 or claim 7, wherein said nitrogen-containing gas is a gas selected from the group consisting of ammonia and  $\text{N}_2$ .
9. A method as claimed in any one of claims 1 to 4 and 6 to 8, wherein said atmospheric gas includes a halogen-containing gas.
10. A method as claimed in claim 9, wherein said halogen-containing gas is a gas selected from the group consisting of  $\text{NF}_3$ ,  $\text{N}_2\text{F}_4$ , HF, chloro-fluoro carbon,  $\text{F}_2$ ,  $\text{Cl}_2$ , HCl, and  $\text{CCl}_4$ .
11. A method as claimed in any preceding claim, wherein said sputtering is RF magnetron sputtering.
12. A method of forming a capacitor comprising:
  - disposing a substrate having an upper surface as a lower electrode and a target of a metal or a metal oxide in a sputtering apparatus;
  - sputtering an oxide film on the lower electrode of said substrate in an atmospheric gas including an oxidizing gas at a proportion not lower than 75%; and

forming an upper electrode on said oxide film.

13. A method of forming a capacitor comprising:  
    disposing a substrate having an upper surface as a lower electrode and a target of a nitride in a sputtering apparatus; 5  
    sputtering a nitride film on the lower electrode of said substrate in an atmospheric gas including a nitrogen-containing gas at a proportion not lower than 75%; and 10  
    forming an upper electrode on said nitride film.
14. A method as claimed in claim 12 or claim 13, wherein said lower electrode, said film and said upper electrode constitute a capacitor of an integrated circuit. 15
15. A method as claimed in any one of claims 12 to 14, wherein said lower electrode, said film and said upper electrode constitute a capacitor of a dynamic memory. 20
